

# Seedling Size and Nursery Spacing

**David South**

Auburn University

- Longleaf pine and many hardwood species are commonly grown at low seedbed densities in bare-root nurseries (10 seedlings per square foot or less). When these species are grown at high seedbed densities ( $>25$  per square foot) then the field performance (survival and growth) is reduced and plantation failure is common.

In New Zealand  
researchers  
recommend  
seedbed  
densities of  
12/sq.ft on  
adverse site s  
and 15/sq.ft. on  
low elevation  
sites.

# Southern Pine Nursery Handbook

May 1985

Root collar diameter  
5.5 mm

- Loblolly pine used by most researchers and landowners are commonly grown in the nursery at high seedbed densities. (more than 25 plants per square foot)
- The trend of lowering seedbed density for loblolly pine and slash pine has been slow. Many landowners have been told that seedling size is unimportant when it comes to improving survival and growth of these species. However, some companies and consultants know this is not true.

# Two Schools of Thought in the South

Size makes no  
difference

Size matters

# Three reasons not to plant low density seedlings

- Some hand planters I know told me they do not like to plant trees with big roots.
- A friend of mine works for a big paper company and he says they do not plant low density trees.
- Seedlings might cost me \$5 to \$7 more per acre.

# Three reasons to plant low density seedlings

- Well balanced seedlings with more roots and more fibrous roots tend to survive better than smaller seedlings with small roots.
- Early growth is usually greater with low density seedlings than with regular bareroot seedlings.
- Value of extra wood harvested at age 13-15 is usually greater than extra cost of \$5 to \$7 per acre.

# Definitions

- Cull seedling
- Plantable seedling
- Grade 2 seedling
- Grade 1 seedling
- Regular seedling
- Target seedling
- Morphologically improved seedling
- Optimum seedling

# "Cull" Seedling

- A "cull" seedling is unacceptable because it does not meet a certain size standard or has a disease or has been injured.
- For loblolly pine, a cull seedling has a RCD of less than 3 mm.

# "Plantable" Seedling

- A "plantable" seedling is defined as a seedling that is slightly bigger than a cull.
- For loblolly pine, a plantable seedling can have a RCD of about 3.2 mm.

# "Grade 2" Seedling

- For loblolly pine, a Grade 2 seedling has a RCD between 3.2 mm and 4.7 mm.

# "Grade 1" Seedling

- For loblolly pine, a Grade 1 seedling has a RCD that is greater than 4.7 mm.

# "Regular" Seedling

- A "regular" loblolly pine seedling is about the size that most researchers use in their tests. Typically has a RCD of about 3.9 mm.

# "Target" Seedling

- The "Target" seedling is defined as the median seedling that nursery managers try to produce the most.
- The "Target" seedling at many nurseries has a RCD less than 5 mm. However, at some nurseries it may be 7 or 8 mm.

# "Morphologically Improved" Seedling

- This seedling is only grown at seedbed densities less than 20 per square foot. At least half of the seedlings have a RCD > 5 mm. This seedling has a higher root-weight ratio than "regular" seedlings and has been cultured to have more fibrous roots. It is not much taller than regular seedlings.

# "Optimum" Seedling

- The "optimum" seedling is defined as

*the ideotype that will minimize overall reforestation costs while achieving established goals for initial survival and growth.*

# Bedding, herbicide (H) and RCD on slash pine survival

South and Mitchell 1999

# Conclusion:

## Size does matter for seedling survival

On average, seedlings grown at low seedbed densities result in about a 5% increase in survival.

(assuming they are handled properly)

# More Growth from Large-diameter seedlings

# Low density trees increase growth in MS

Autry 1972

# Low density trees increase growth (age 8) in GA

South, Rakestraw and Lowertz 2001

# Seedling grade study at Hodge, LA (age 13)

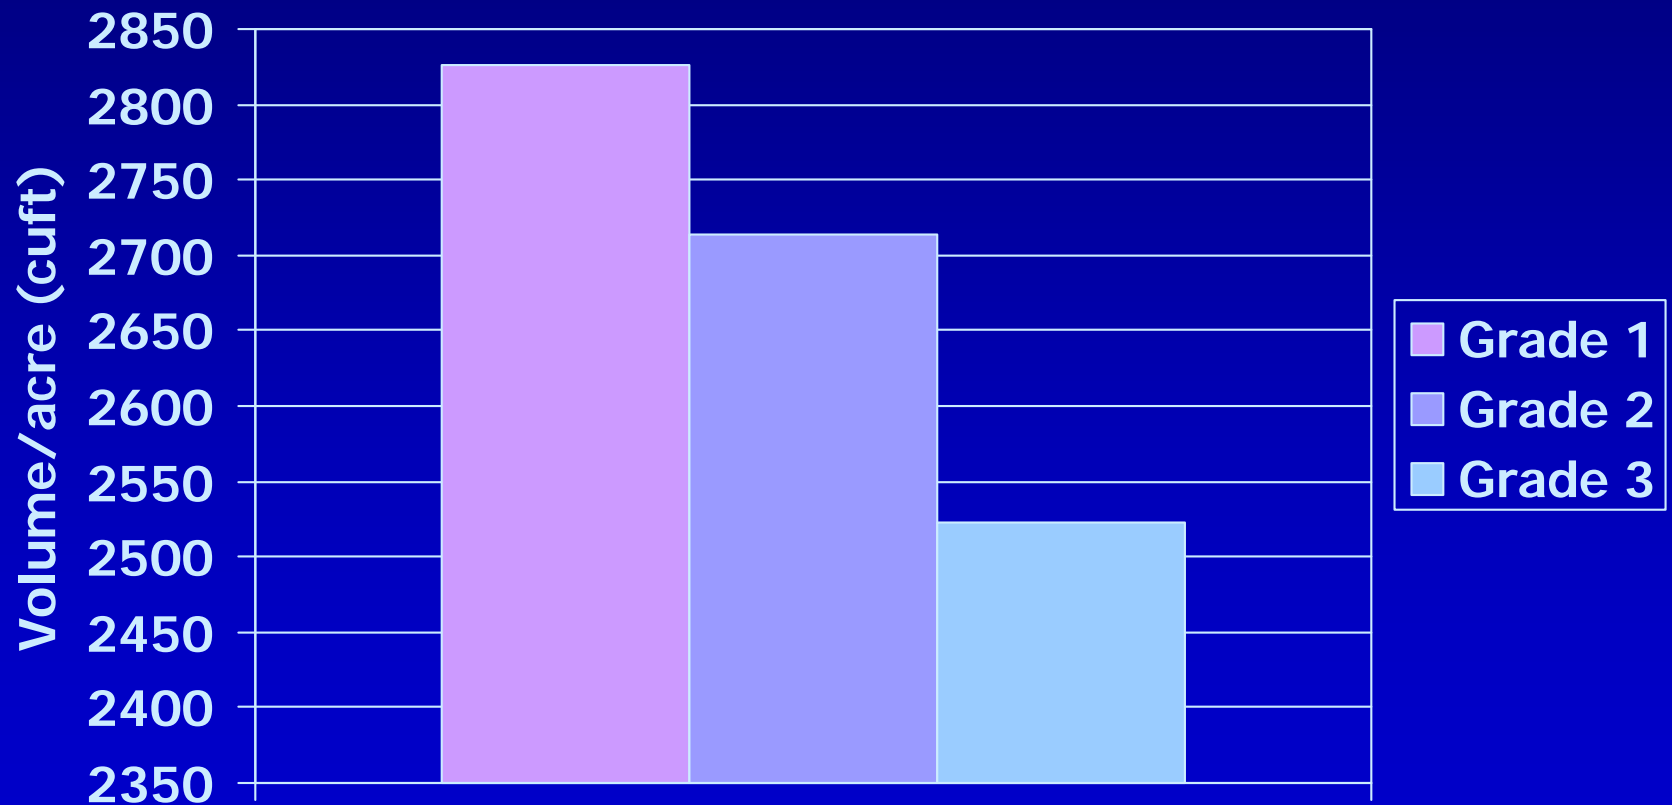

856 more cubic feet with Grade 1 seedlings

South, Boyer and Bosch 1985

# Seedling grade study at Bellville, GA (age 13)

112 more cubic feet with Grade 1 seedlings

South and Rakestraw 2002

# No genotype by grade interaction

Cubic feet per acre

South and Rakestraw 2002

Conclusion:  
Size does matter for  
seedling growth

How much does it cost?  
And can I profit from planting  
morphologically improved  
seedlings?

Low density seedlings  
may cost \$11 more per  
thousand seedlings

### 2002-03 Price List

Species	Code	Description	\$ per Thousand*
Loblolly Pine	03	1.5 generation rust-resistant, Coastal	\$43
Loblolly Pine	09	2.0 generation rust-resistant, Coastal	\$44
Loblolly Pine	13	2.0 generation low-density, Coastal	\$55

Cost/acre of low-density trees is  
the same when machine planting  
plant fewer trees

625 regular = 500 low density

544 regular = 435 low density

500 regular = 400 low density

# A quick look at costs

1.1 cents more per tree

Assume machine planting

12' x 12' spacing = \$3.33 more per acre

12' x 10' spacing = \$4.00 more

12' x 9' spacing = \$4.44 more

12' x 8' spacing = \$5.00 more

12' x 7' spacing = \$5.70 more

12' x 6' spacing = \$6.65 more

# Hamilton Ridge site

- Survival was high 93.5% for both ideotypes.
- When comparing alternative methods of establishment, planting low-density seedlings (in this case) can achieve the same response as planting 5 mm seedlings and investing \$173/acre in intensive management.

# Conclusions

- Gains in survival and growth can be achieved by planting low-density seedlings (machine planting recommended)
- Per seedling costs are higher for low-density seedlings than for regular seedlings but the benefit/cost ratio can be substantial
